BITSS Annual Meeting, December 2017

Dynamic Documents for computational reproducibility

One Type of Dynamic Document: R Markdown

Practical Exercise

Final Remarks & More Resources

Dynamic Documents for computational reproducibility

Dynamic Documents for computational reproducibility

- ▶ Based on principles of *literate programming* aims at combining code and paper in one single document
- ▶ Best framework to achieve the holy grail of **one-click reproducible workflow**
- ▶ Best two current implementations: RMarkdown (R) & Jupyter (Python). Stata is catching up (more at the end)

Currently code and narrative components live in separate universes

Dynamic Documents: integrate the two universes!

Paper + Code

Dynamic Documents: A Recipe

- ▶ 1 simple language that can combine text and code: Markdown
- ▶ 1 statistical package to do the analysis (R, Python, 3S's?)
- ▶ 1 machinery to combine analysis and text to create a single output: Pandoc
- ▶ [Optional-but-not-really] 1 program to bring all the elements together: RStudio/RMarkdown, Jupyter

One Type of Dynamic Document: R Markdown

For our exercise: R Markdown

- ▶ R: **open source** programming language design for statistical analysis.
- ▶ RStudio: free software that provides an Integrated Development Environment (IDE)
- ▶ RStudio combines all together: R + Markdown + Pandoc to produce multiple outputs

R Markdown

Basic Structure

- ▶ A header
- ▶ Text
- ▶ Code: inline and chunks

Basic Structure: Header

```
---  
title: "Sample Paper"  
author: "Fernando Hoces de la Guardia"  
output: html_document  
---
```

Basic Structure: Body of Text

```
---  
header  
---
```

This is where you write your paper. Nothing much to add. You can check Markdown syntax [here](#). And it can use can type equations using LaTeX syntax!

Basic Structure: Code Chunks and Inline

```
---  
header  
---
```

Body of text.

To begin a piece of code (“code chunk”). Enclose them in the following expression (Ctrl/Cmd + shift/optn + i)

```
```{r, eval=TRUE}  
here goes the code
```
```

To write inline use only one backtick to open followed by an “r” and one to close ‘r 1+1’ in the output.

Practical Exercise

Hands-on exercise: the birthday problem!

As an illustration let's write a report using the participants in this workshop to illustrate the famous birthday paradox.

What is the probability that at least two people in this room share the same birthday?

Is it something like $\frac{1}{365} \times N = 0.11$?

Create a new RMarkdown File

- 1 - In RStudio: File-> New File -> RMarkdown...
- 2 - Name it, and save it.
- 3 - Review/edit the header, and delete all the default body of text except for one code chunk.

The birthday problem: the math

Actually the math says otherwise:

$$\begin{aligned}1 - \bar{p}(n) &= 1 \times \left(1 - \frac{1}{365}\right) \times \left(1 - \frac{2}{365}\right) \times \cdots \times \left(1 - \frac{n-1}{365}\right) \\&= \frac{365 \times 364 \times \cdots \times (365 - n + 1)}{365^n} \\&= \frac{365!}{365^n(365 - n)!} = \frac{n! \cdot \binom{365}{n}}{365^n}\end{aligned}\tag{1}$$

$$p(n = 40) = 0.891$$

Code for the math

Don't look at this: just copy and past into your report

```
\begin{align}
1 - \bar{p}(n) &= 1 \times \left(1 - \frac{1}{365}\right) \\
&\times \left(1 - \frac{2}{365}\right) \times \cdots \times \\
&\left(1 - \frac{n-1}{365}\right) \text{ \nonumber \\
&= } \frac{365 \times 364 \times \cdots \times \\
&\quad (365-n+1)}{365^n} \text{ \nonumber \\
&= } \frac{365!}{365^n (365-n)!} = \\
&\quad \frac{n! \cdot \text{binom}\{365\}\{n\}}{365^n} \\
p(n = \text{`r n.pers`}) &= \text{`r} \\
&\quad \text{round}(1 - \text{factorial}(n.\text{pers}) * \\
&\quad \quad \text{choose}(365, n.\text{pers}) / 365^{n.\text{pers}}, 3) \text{ \nonumber} \\
\end{align}
```

Don't like math? Let's run a simple simulation!

- 1 - Simulate 10,000 rooms with $n = 40$ random birthdays, and store the results in matrix where each row represents a room.
- 2 - For each room (row) compute the number of unique birthdays.
- 3 - Compute the average number of times a room has 40 unique birthdays, across 10,000 simulatinos, and report the complement.

Code for the simulation

```
birthday.prob = function(n.pers, n.sims) {  
  # simulate birthdays  
  birthdays = matrix(round(runif(n.pers * n.sims, 1, 365)),  
                      nrow = n.sims, ncol = n.pers)  
  # for each room (row) get unique birthdays  
  unique.birthdays = apply(birthdays, 1, unique)  
  # Indicator with 1 if all are unique birthdays  
  all.different = (lapply(unique.birthdays, length) == n.pers)  
  # Compute average time all have different birthdays  
  result = 1 - mean(all.different)  
  return(result)  
}  
n.pers.param = 43  
n.sims.param = 1e4  
birthday.prob(n.pers.param, n.sims.param)
```

```
## [1] 0.9221
```

Results

- ▶ Many people originally think of a prob $\sim \frac{1}{365} \times N = 0.118$
- ▶ However the true probability is of $p(n = 43) = 0.924$
- ▶ And the simulated probability is of 0.9273

Final Remarks & More Resources

Final Remarks & More Resources

- ▶ With DD with can achieve a one-click reproducible workflow.
- ▶ This is particularly helpful to understand/present results that are hard to digest.
- ▶ Stata just develop an internal version of DD for v15. Review [Here](#)
- ▶ Want to learn more: great free books (can you guess how they were written?)
